**The SCC Algorithm : A shorter Proof**

---

The subject is the Strongly Connected Components algorithm of Kosaraju and Sharir [1978] that appears in section 22.5 of [CLRS], and its proof of correctness. For the sake of completeness, we repeat the algorithm below (slightly rephrased).

**STRONGLY-CONNECTED-COMPONENTS ( $G$ )**

1. initialize stack  $S$  to empty, and call DFS( $G$ ) with the following modification: push vertices onto stack  $S$  in the order they finish their DFS-VISIT calls. That is, at the end of the procedure DFS-VISIT( $u$ ) add the statement  $PUSH(u, S)$  (there is no need to compute  $d[u]$  and  $f[u]$  values explicitly).
2. construct the adjacency-list structure of  $G^T$  from that of  $G$ .
3. call DFS( $G^T$ ) with the following modification: initiate DFS-roots in stack-S-order, ie, in the main DFS algorithm instead of  
“for each  $u \in V[G^T]$  do if  $color[u] = white$  then DFS-VISIT( $u$ )”

perform the following:

- ```

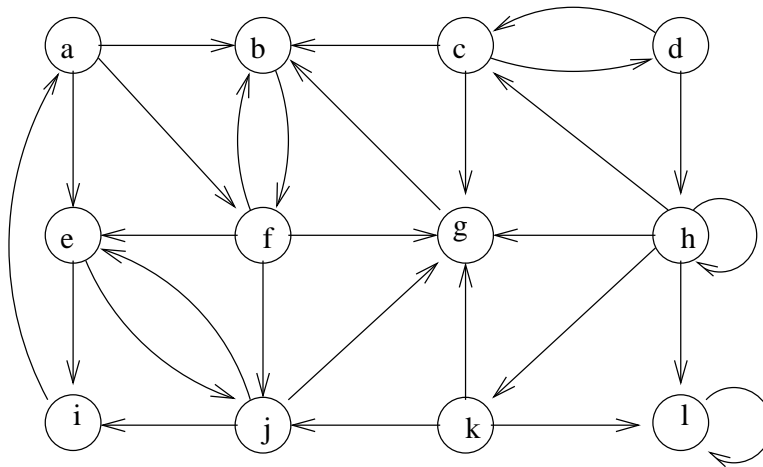

while  $f \neq \emptyset$  do
   $u \leftarrow POP(S)$ 
  if
    end {w
4. each DFS
end

```
- <https://eduassistpro.github.io/> forms an SCC.

(e) SCC-Component dag of  $G$ :

### Proof of Correctness:

The correctness proof given in the book takes 4 pages. We give a shorter proof by using Theorem 23.6 (Parenthesis theorem), its Corollary 23.7, and Theorem 23.8 (White-path theorem). As we proceed, we will jump back and forth between the DFS( $G$ ) of step 1 and DFS( $G^T$ ) of step 3. The reader should keep the distinction in mind.

The fact that the algorithm takes  $\Theta(V + E)$  time is obvious. Let us consider its correctness. First a few notations:

- Let  $u \xrightarrow[G]{\sim} v$  mean vertex  $v$  is reachable from  $u$  in  $G$ , ie, there is a directed path in digraph  $G$  from  $u$  to  $v$ .
- Similarly, let  $u \xleftrightarrow[G]{\sim} v$  denote  $(u \xrightarrow[G]{\sim} v) \& (v \xrightarrow[G]{\sim} u)$ , ie, vertices  $u$  and  $v$  are mutually reachable from each other in  $G$ .
- The  $\xleftrightarrow[G]{\sim}$  relationship is reflexive, symmetric, and transitive. Hence for each pair of vertices  $u$  and  $v$ ,  $u \xleftrightarrow[G]{\sim} v$  iff  $u \xleftrightarrow[G^T]{\sim} v$  iff  $u$  and  $v$  are in the same SCC, and the latter implies that no directed path between  $u$  and  $v$  ever leaves the vertices of their SCC.
- In what follows, for each vertex  $u$ , let  $d[u]$  and  $f[u]$  *always* denote the start and finish times of DFS-VISIT( $u$ ) with respect to the first DFS in step 1 of the algorithm (even while we refer to some events in the second DFS in step 3).

Consider an arbitrary vertex  $x$  of the SCC visited by the DFS. By the white-path theorem, all vertices of the SCC are reachable from  $x$ , thus the DFS-tree of step 1 contains all vertices of the SCC in a single DFS-tree.

What remains to prove is that each DFS-tree of step 1 contains all vertices of the SCC in a single DFS-tree.

Let  $T$  be a DFS-tree of DFS( $G^T$ ) in step 3. We want to show that all vertices of the SCC are mutually reachable in  $G$  (and equivalently in  $G^T$ ). Let vertex  $x$  denote the root of  $T$ . Because of the transitivity and symmetry of  $\xleftrightarrow[G]{\sim}$ , it suffices to show that for every vertex  $v \in T$ ,  $v \xleftrightarrow[G]{\sim} x$ .

Since  $x$  is the root of  $T$ , we conclude:

$$x \xrightarrow[G^T]{\sim} v \quad \forall v \in T \quad (1)$$

Also, since  $x$  is the root of  $T$ , the stack-S-order selection during the DFS( $G^T$ ) implies that:

$$f[x] \geq f[v] \quad \forall v \in T \quad (2)$$

That is  $f[x]$  is maximum among vertices of  $T$ . (Once again,  $f[.]$  is w.r.t. the DFS( $G$ ) of step 1, not step 3!)

Let vertex  $y \in T$  have the minimum  $d[.]$  value among the vertices in  $T$ . That is:

$$d[y] \leq d[v] \quad \forall v \in T \quad (3)$$

We know that  $y$  is a descendent of  $x$  in  $T$ . Let  $P$  denote the path of tree edges in  $T$  (and in  $G^T$ ) from  $x$  down to  $y$ . Existence of path  $P$  in  $G^T$  implies that  $x \xrightarrow[G^T]{\sim} y$ . The latter is equivalent to  $y \xrightarrow[G]{\sim} x$ . Because of eq. (3), during DFS( $G$ ) of step 1 we know that at time  $d[y]$  every vertex on the path  $P$  is white. Therefore, by the white-path theorem,  $x$  is a DFS-descendent of  $y$  in

DFS(G) of step 1. Hence, because of the parenthesis theorem and its corollary, we conclude that  $f[y] \geq f[x]$ . This and eq. (2) imply that  $f[x] = f[y]$ , and hence  $x = y$ . From the latter and eqs. (2) and (3) we conclude:

$$d[x] \leq d[v] < f[v] \leq f[x] \quad \forall v \in T \quad (4)$$

Because of the parenthesis theorem and eq. (4), we conclude that for every vertex  $v \in T$ ,  $v$  is a DFS-descendent of  $x$  in DFS(G) of step 1. This implies that

$$x \xrightarrow[G]{} v \quad \forall v \in T \quad (5)$$

From eqs. (1) and (5) we conclude

$$x \xleftrightarrow[G]{} v \quad \forall v \in T \quad (6)$$

That is, all vertices of  $T$  are in the same SCC.  $\square$
